

Nobel for Detecting Gravitational Waves

Why in news?

\n\n

Rainer Weiss, Barry C. Barish's and Kip Thorne's were jointly awarded the Nobel Prize for physics for their contribution to the LIGO-VIRGO project and its detection of gravitational waves.

\n\n

What is project about?

\n\n

\n

- **Research** - Laser Interferometer Gravitational Wave Observatory - LIGO was built in the US to detect gravitational waves.

\n

- In collaboration with Italy based VIRGO observatory, LIGO detected gravitational waves for the first time in 2015.

\n

- Since then, the LIGO-VIRGO collaboration has detected such signals four times.

\n

\n\n

\n

- **Concept** - Gravitational waves are ripples in space.

\n

- It is caused by cataclysmic events that result in high-energy explosions, such as collision of black holes or neutron stars.

\n

- When these disturbances reach far-off regions, the signals become weak and require extremely sensitive detectors to sense them.

\n

- **Significance** - The first detection made in 2015 revealed the merger of two black holes - 1.3 billion years ago.

- \n
- Hence, gravitational wave observations could unravel many more mysteries pertaining to the early days of the universe's existence.
- \n
- Gravitational wave astronomy is hence a science of the near future whereby black holes, neutron stars may be mapped.
- \n

\n\n

How does the future look?

\n\n

- \n
- The advantage of having multiple detectors is that the location of the source can be determined more accurately.
- \n
- More observatories are in the pipeline to add to the current 3 of which 2 belongs to LIGO & 1 to VIRGO.
- \n
- The Japanese KAGRA detector is set to go online in 2019 and LIGO India set to join by 2024.
- \n
