

## The Case for “Green GDP”

### What is the issue?

\n\n

\n

- Development sans environmental preservation is a mirage.
- Hence, India must calculate its “Green GDP” to factor in the value of the environment in its growth.

\n

\n\n

### What are the environmental impacts of development?

\n\n

\n

- A recent World Bank report states that it cost India about \$550 billion amounting to about 8.5% of its GDP, due to air pollution.
- Experts have also vouched that the cost of externalities due to water pollution and land degradation were possibly far higher.
- Our disregard for environment in pursuit of advancing economic development is raising the risk of desertification and land degradation significantly.
- Not surprisingly, estimates are that our food production could see a loss of 10-40% if these trends continue unabated.
- While natural capital like water and clean air is self regulating, it needs to be handled sustainably in order to avoid depletion.
- For this, it is crucial to understand the environmental footprint of our economic activities, which also needs to be accounted in our GDP.

\n

\n\n

## **How can environmental footprint be accounted in GDP?**

\n\n

- \n
  - Natural capital can cover entire ecosystems such as fisheries and forests, besides multiple other hidden and overlooked ecological services.
  - \n
    - Regeneration of soil, nitrogen fixation, nutrient recycling, pollination and the overall hydrological cycle are all components of natural capital.
    - \n
      - Valuing such ecosystem services is challenging as these aspects can't be monetised directly, but their depletion does reduces productivity.
      - \n
        - Giving a monetary value to this depreciation to natural capital is also not exactly possible as the numbers are interpretative in nature.
        - \n
          - To address these issues, concepts like “environmental Kuznets curve” that plots “per capita GDP” against “Sulphur dioxide concentration” in the local air have been put forward.

\n\n

## **What are the possible dangers?**

\n\n

- \n
  - India routinely suffers from high levels of air pollution that impose costs on local transport, health and liveability in urban and rural areas.
  - \n
    - When economic growth leads to the destruction of forests, wetlands, mining or even urban expansion, it is typically the poorest who suffer.
    - \n
      - Full-scale ecological collapse is already visible in the Darfur region of Sudan and countries in the Horn of Africa.
      - \n
        - Indian people and policy makers need to act immediately and coherently to arrest such rapid socio-economic decline.

\n\n

## **What have been the significant efforts taken thus far?**

\n\n

\n

- India's current national accounts already do incorporate such environmental considerations in a limited fashion but it is not comprehensive.

\n

- In this context, it was planned in 2013 to release a comprehensive "Green GDP" estimate in 2013, and the various departments started working on it.

\n

- But lack of micro level data on natural capital formation (and destruction), proved a major constrain and the exercise never saw completion.

\n

- The 12th Five Year Plan undertook groundwater resource mapping at the national level, which was indeed a significant exercise

\n

- Similar comprehensive exercises are now essential for data on land usage, forests and mineral wealth.
